"Trillinos used in DRT"

"DRT discretization management"

Michael W. Gee

Lehrstuhl für Numerische Mechanik

Prof. Dr.-Ing. Wolfgang A. Wall

TU München

Why c+ + and Trilinos and a new discretization management?

- Our applications become much more complex and we need to reuse and integrate our groups research achievements to a much larger extend then before
- We have to become 'organized' meaning we need clearly defined modules and objects that we can easily combine to create new methods.
- (Xfem/Mortar/Chimera turbulaent FSI with thermo coupling in biomechanical tissue contact with noise scattering in the throat of whales or so....)
- discretization (we will have a new worst but hopefully smaller bottleneck after this...) Our current worst bottleneck is the inflexibility and inefficiency or the current
- Another bad bottleneck is the explicit dependency on GID.
- be fortran90/95), and C is not. Python, Java, Matlab etc. are not suitable for one or the c++ is *one* appropiate language to pursue and achieve these goals (the other would other reason, mainly performance.
- We outsource all parallel linear (and nonlinear?) algebra to Trilinos:
- Trilinos is $\mathsf{c}++$ at the user/developer level and fortran77/c at the kernel
- Trilinos is LGPL
- Trilinos is close to our style of parallel thinking (dom. decomp., MPI)
- Trilinos is very powerful and very mature in all basic subpackages
- Integrating the mature Trilinos basic subpackages (Epetra, AztecOO, NOX, ML, Ifpack, Amesos, Teuchos) lets us easily play with the less mature but maybe useful other packages as well (Rythmos, Loca, Meros, Anaszasi, Thyra, PyTrilinos)

Some of the C++ features unfamiliar to C

```
cout/new/delete/string/{}/bool/namespaces/reference/files/
                                          overloading
```

Classes

```
/ pure virtual classes / inheritance
basic classes / public, private, protected
                                 virtual classes
                                                                 casting
```

Templates & STL

```
templates / vector / map / multimap / iterators
```

Reference counting pointer and parameter list (Trilinos)

```
RefCountPtr / ParameterList
```

Epetra parallel linear algebra objects (Trilinos)

```
Epetra_Comm / Epetra_Map / Epetra_Vector
                                 Epetra_CrsMatrix
```

```
InM
```

```
// declaration
namespace DRT;
{
   void Myfunction(...);
   void Myfunction2(...);
}
// definition
void DRT::Myfunction(...)
{
   // whatever this function does
   return;
}
// usage:
DRT::Myfunction(...);
// or:
using namespace DRT;
Myfunction(...);
// or:
```

```
// often, more abstract objects 'implement the ostream <<' operation
                                                                                                                                                                                    = " << 1+5 << endl;
                                                                                                                                                                                                                                                                                                           ostream& operator << (ostream& os, const DRT::Element& ele)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              printf("In %d cases, c is more convenient to print\n",5);
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   // often it is more convenient to do c-style printing
                                                                                                                                                                                     ;
>>
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       // there is also stuff like cin, cerr etc....
                                                                                                                                                                                     2
                                                                                                                                                                                      V
                                                                                                                                                                                     ;
+

-> the synthax for i helps the compiler determine that nobody messes with i
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  -> sum exists only inside the loop (making this loop somewhat useless)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          // note that a variable exists only in the {} where it was declared
                                                                                                                                                                                                                                                                                                                                                                     double d = c; // this is wrong, c does not exist here
// in a c++ code you can define a variable at any place
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              -> i exist only inside the loop
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       -> c exists only inside its {}
                                                                                                                                                                                                                                                                                                                                                                                                                                       for (int i=0; i<10; ++i)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  double sum = a+b+d;
                                                                                                                                                                                                                                                            double c = a+b;
                                   void myfunction(....
                                                                                                                                               double b = 7.0;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          sum *= i;
                                                                                                                 II
                                                                                                          double a
```

```
void myfunction(....)
{
    // c-style reference
    int i = 5;
    int i = 5;
    int = 7;
}

{    // c++ style reference
    int i = 5;
    int i = 5;
    int i = 5;
    int j = 13;
    // wrong! not referencing
    // anything, won't compile
    int& jref;
    jref;
    jref;
    jref;
    jref;
    jref;
}
```

Note

Unlike fortran, c only has call-by-value. If you need a call-by-reference, a call-by-value on the adress of an object is made

c++ has a true call by reference (reference operator &)

One can not have a reference variable not referencing anything. This way, a reference (unlike a pointer) is always well defined and valid.

```
void myfunction(....)
{
   // c-style call-by-reference
   int i = 5;
   AddTwo(int* i)
{
   *i += 2;
   return;
}

void myfunction_cpp(....)
{
   // c++-style call-by-reference
   int i = 5;
   AddTwo_cpp(int& i)
}
AddTwo_cpp(int& i)
{
   i += 2;
   return;
}
AddTwo_repo(int& i)
}
i += 2;
return;
}
```

Don't have to mess with all this pointer/adress business, just use a call by reference or a call by value

Cannot have bad references as one can have bad pointers

A reference is always 'good' otherwise the compiler notices.

```
node.H
```

```
// doxygen docu of nodefunction1
                                                                                                                                                                   // doxygen docu of nodefunction2
                                                                                                                                                                                                                                          #endif // end of header file
// file description comment
                                                                                                                                        void nodefunction1(...);
                                                                                                                                                                                        int nodefunction2(...);
                                                                                               // some declarations
                   #ifndef NODE_H
                                             #define NODE_H
```

of node. H are ok due to NODE_H multiple and nested inclusions

```
c++ does not tolerate multiple
                           declarations
```

node.cpp

```
#include"headthatincludesnodeaswell.H"
                                                                                                                                     // short comment on nodefunction1
// file description comment
                                                                                                                                                                      void nodefunction1(...)
                                #include "node.H"
```

// short comment on nodefunction 2

int nodefunction2(...)

```
node.H
```

```
// file description comment
#ifndef NODE_H
#define NODE_H

// some declarations

// some declarations

void TwiceThis(const int& i);

void TwiceThis(const double& i);

#endif // end of header file
```

Overloading can help save brain power
 (Just remember there was a TwiceThis method that worked for all reasonable data types)

- Be very reasonable, one can do a lot
of nonsense with overloading..., e.g.
void TwiceThis(const double& i)
{
 i = i*i;
}

```
node.cpp
```

```
// file description comment
#include "node.H"
#include"headthatincludesnodeaswell.H"
// short comment on AddThis
```

```
// short comment on AddInis
void TwiceThis(const int& i)
{
    i = i*2;
}
// short comment on AddIhis
void TwiceThis(const double& :
    i = i*2.0;
}
```

Some of the C++ features unfamiliar to C

```
cout/new/delete/string/{}/bool/namespaces/reference/files/
                                              overloading
```

<- We are here now ->

Classes

```
/ pure virtual classes / inheritance
basic classes / public, private, protected
                                 virtual classes
                                                                 casting
```

Templates & STL

```
templates / vector / map / multimap / iterators
```

Reference counting pointer and parameter list

```
RefCountPtr / ParameterList
```

Epetra parallel linear algebra objects

```
Epetra_Comm / Epetra_Map / Epetra_Vector
                                 Epetra_CrsMatrix
```

Outline "Jump-start C++" & "Trilinos used in DRT"

```
myanimal.privk_ = 13; // won't compile
                                                                                                                                                                                                                                                                                                                                                                                                                                                      // or derived from Animal here (later)

```

A function inside a class is called a method.

All methods can access private/protected data.

```
// create an instance of Animal
Animal myanimal;
myanimal.pubi_ = 5; // ok
// might be ok if i'm either
// a friend of Animal
// or derived from Animal here (later)
myanimal.protj_ = 7;
// ok, note that k is a copy of
// privk_ !
double k = myanimal.Returnk();
```

Private/Protected data can only be accessed (read/write) by the class' own methods

One can also have private methods, that can only be called by other methods of the class

```
myanimal.ReturnKRef() = 17; // nice?
                                                                                                                                                                                                                                                                                                                      *(myanimal.AccessI()) = 7; // nice?

                                                                                                                                                                                                                                                                                                                                                                                                         // do not want copy-ctor
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     }; // end of class Animal
                                                                                                                                                                                                                                                                                                  MyMethod(int fool);
                                                                                 // constructor
                                                                                                     Animal(int j);
                                                                                                                                                                                                              // destructor
class Animal
                                                                                                                                                                                                                                  ~Animal();
                                                                                                                                                                 Animal();
                                                                                                                                                                                                                                                                                                                                           protected:
                                                                                                                                                                                                                                                                                                                                                                private:
                                       public:
```

```
namespaces are ALL capital, e.g.
                                namespace DISCRETIZATION
```

```
classes are captial and small, e.g.
                                   class LineElement;
```

```
Methods and functions are
                             capital and small, e.g.
```

```
variables and instances are ALL
                   small, e.g.
                                          int i;
```

```
variables/instances inside classes
                                                                                      end with an underscore, e.g.:
Solid3 myelement(...);
                                                                                                                         class Animal
```

```
Node& mynode_;
int i_;
```

Design a class that describes a Person

```
class Person
```

}; // end of class Person

```
class Element
{
   Element(int id, int nnode, int* nodeids);
   Element(const Element& old);
   virtual ~Element();
   virtual int Id()
   { return id_; }
   virtual int* NodeIds()
   { return node_; }
   virtual int* nodeids_; }

protected:
   int id_;
   int id_;
   int id_;
   int node_;
   int* nodeids_;
   int* nodeids_;
```

A virtual class is basically a class that declares at least its destructor 'virtual'

Now, we need about x different types of elements (shell, fluid3, solid3, ale2 ...)

We could:

- store ALL of their specific data in Element
- Create a separate Element class for each of them and make the discretization handle them all (a lot of if's and switches)
- use derived classes
- other ways not discussed here...

```

                                                                                                                                                                         (...) // other stuff
                                                                                                                                                                                                                          // do not want these
                                                                                                virtual ~Animal();
class Animal
                                          Animal();
```

'Animal' is pure virtual, one can not have an instance of Animal:

class Hbee : public Animal

Hbee(const Hbee& old);

Hpee();

virtual ~Hbee();

```
{
   Animal myanim; // this will not compile
}
```

int Nlegs() { return 6; }

Animal is ment to derive from, you can not use Animal itself

classes: pure virtual classes 5

Hbee operator = (const Hbee& old);

}; // end of class Hbee

Hbee(const Hbee& old);

// do not want these

private:

                                                                                                                                                                                                                                                                                                                                   function is used:
                                                                                                      return data;
```

- One can have template functions, methods and classes
- Bugs in templates can be very hard to find, they are hard to debug and often produce very kryptic compiler/linker messages leaving no clue what the problem might be.
- Usage of templates (especially those from the STL) is desired in \$CODENAME
 - Creation of templates is in general not encouraged as they can be very hard to understand for (future) coworkers
 - Create templates iff you feel absolutely comfortable with them!

c++ comes along with a series of very powerful and useful templates we should

```
vector<double> x(5); // constructor with a given size
excessively use. These are bundled in the so called STL
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    // x dies correctly when the destructor of vector is
                                                                                                                                                                                                                                                                                                                                                    if (!x) cout << "Error: Allocation failed\n";</pre>

#include <vector>
                                                                                                                                                                                                                                                                                                                                  // better:
                                                                     // bad:
```

- A vector can hold anything, even another templated something
- A vector calls the destructor of the data objects in the vector upon deletion, (it does NOT call delete on pointers)

the Standard Template LIB (STL) 4

map is a 'pair associative container':

```
5 with pi, no 0,1,2,3,4 exist!
                                                                                                                                                                                                                                                                                                                              // associates element ptrs with an int key
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         map<string, vector<double> > myvectors; // vectors with a certain name mvvectors["solution"].resize(10); // vector "solution" now of length 10
                                                                                                                                                                                             data.insert(pair<int,double>(9,2.7)); // the long way to insert something
                                                                                                                                                            // associates 7 with 2pi
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   // we leaked nothing here, everything was destroyed correctly
                                                                                                                           // associates
                                                                                                                                                                                                                                                               int dim = data.size(); // number of pairs in data
                                                                                                                                                                                                                                                                                                                                                                                                                                                                   // Something a little bit more complex:
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   myvectors["solution"].resize(10);
myvectors["solution"][5] = 3.141;
                                                                                                 map<int,double> data;
                                #include <vector>
#include <map>
```

- data in a map is associated with a key that can also be of any type
- data in a map is NOT contigous (its actually stored in a tree for fast access)
 - how do I get my stuff out of a map if I do not know what's exactly in there?

map comes with something called an 'iterator'

```

#include <map>
```

Some of the C++ features unfamiliar to C

```
cout/new/delete/string/{}/bool/namespaces/reference/files/
                                          overloading
```

Classes

```
/ pure virtual classes / inheritance
basic classes / public, private, protected
                                 virtual classes
                                                                 casting
```

Templates & STL

```
templates / vector / map / multimap / iterators
                                                  <- We are here now at the end of the c++ language part ->
                                                                                                              Reference counting pointer and parameter list
                                                                                                                                                                          RefCountPtr / ParameterList
```

Epetra parallel linear algebra objects

```
Epetra_Comm / Epetra_Map / Epetra_Vector
                                 Epetra_CrsMatrix
```
